Accounts and Cards

A fiat rail the network runs: accounts, cards, and fiat in and out over MOR and stable balances. The smallest dependency in the set. It needs nothing else here to be useful.

The problem, in their numbers. MOR trades about \$8.9k in a day [verified]. DEX depth is about \$1.4M, and 88.8% of it is protocol-owned in one Safe [verified]. A provider earning MOR has no fiat exit the network runs. To turn MOR into rent or payroll they leave for an exchange and a bank Morpheus does not operate, and they sell into that thin book. `api.mor.org` is OpenAI-compatible, so a Web2 customer buys inference without a wallet [verified]; but that customer keeps no balance, holds no card, draws no statement. The rail that carries inference stops at the wallet boundary. Every real customer crosses it by hand.

The fix. `luxfi/bank` is that edge, and it is built. One Go service, `bankd`, on Hanzo Base, with auth, storage, and an admin console beneath it. It holds accounts, individual and business, with multi-currency balances tracked as available and held. It issues virtual cards behind a KYC and consent flow, quotes and executes fiat/crypto exchange, and takes deposits and sends. Fiat moves over CurrencyCloud and IFX. KYC, AML screening above the reporting threshold, and sanctions and PEP checks run as record-level hooks in the write path, not a layer bolted on after. Custody is three questions kept separate (`COMPLIANCE.md`): who holds the signing key, where the asset sits, who may freeze or reissue. A self-custody deployment leaves the customer holding their own key; bank records rather than signs. Everything answers under `/v1/bank`, so the gateway gains a fiat rail without a second API host.

The outcome, quantified. A fiat on/off-ramp the network runs. Today MOR's only exit is a DEX clearing about \$8.9k a day against about \$1.4M of mostly protocol-owned depth [verified]. A provider drawing more than pocket change cannot cash out at scale. bank routes fiat over CurrencyCloud and IFX, independent of DEX depth, so a provider's off-ramp stops being bounded by that book: draw MOR to a card or a bank account, hold a stable balance, spend it. bank is also the smallest thing to adopt. It depends on nothing else in the set, so it ships first and de-risks the rest, and it is the custody leg ADOPT-04 lends against.

Assumptions, stated

- Reach converts. The 100,000,000+ launch reach across Hanzo and Zoo surfaces [client] feeds the funnel that fills accounts [illustrative]. Not promised; the condition under which the rail fills.
- The KYC base carries. Users onboarded through Hanzo IAM and `lux/wallet` [verified repos] enter bank's compliance path without a second onboarding.

Relevance. bank already exists, carries compliance in the write path, and its self-custody deployment means Morpheus never holds a key. The Hanzo IAM and `lux/wallet` identity the funnel fills is the same one bank onboards, so the fiat edge and the demand that makes it worth having land on one base.

What this does not solve. An edge is not the settlement layer. bank holds and moves balances; it does not price inference, prove it happened, or move MOR across chains. Which licenses apply in a given jurisdiction is a question for counsel, not code. And a card is worth most once there is revenue to draw against it: bank is useful the day it ships, most valuable once real inference revenue flows through the gateway (ADOPT-07).

ADOPT-05. Component `luxfi/bank`, live. The custody leg ADOPT-04 builds on; most valuable once ADOPT-07 demand flows. • `research@lux.network`
